SOURCE OF DATA

Method of Study

On March 1, 1932, an accounting study of the organization and operation of twenty-four farms in Stevens County was started under the joint supervision of the Division of Agricultural Economics of the University of Minnesota, the West Central Agricultural Experiment Station, and the Bureau of Agricultural Economics of the United States Department of Agriculture. Mr. Frank Douglass, County Agricultural Agent, and Mr. Allen W. Edson of the West Central Agricultural Experiment Station assisted in selecting farms that were representative of the types of farming found in the area.* The farmers cooperating in this study keep a complete record of cash receipts and cash expenditures, a daily record of the labor used on each crop and class of livestock, a record of the farm produce used in the house, and other detailed information regarding the farm business. These records are checked at least twice per month by the route man and supplemented with inventories, livestock feed records, reports of crop yields and practices and other significant facts about the farm operations. The data collected are sent to the central office at University Farm, St. Paul, where a detailed set of records for each farm is kept. From these records, this report on livestock costs and returns for 1933 was prepared. A summary of costs and returns for both livestock and crops will be published as Mimeographed Report No. 65.

Feed Situation in 1933 Unfavorable for Livestock Production

The severe drouth in 1933 resulted in extensive crop failure and a shortage of pasture. Generally speaking, the feed that was produced was below normal

*For a description of the area and the farms studied, see A Preliminary Report of Crop Costs and Returns, Mim. Rept. No. 61, Division of Agricultural Economics, University of Minnesota.

in quality. Little feed was available for purchase, prices were high and the credit necessary for buying feed was hard to obtain. As a result, rations for livestock were reduced and farm animals were in much poorer condition at the end of the year than at the beginning. Practically no fattening of cattle was done, other than to finish those that were on feed at the beginning of the year. Many pigs were sold during the emergency pig-buying program and other hogs were marketed at lighter than usual weights. The low prices for cows together with the expectation of the establishment of a dairy production control program led many farmers to retain cows that normally would have been disposed of because of the feed shortage.

Generally speaking, the prices received for livestock and livestock products in 1933 were higher than in 1932.

METHODS OF COMPUTING AND PRESENTING DATA

The comparative costs and returns for each of the different classes of livestock maintained in 1933 are presented in this preliminary report. All data are shown on the basis of a standard unit such as one head or 100 pounds gain in weight. Both quantities--pounds of feed, days of pasture, man and horse hours, pounds produced, etc.--and money costs and returns are shown. The amounts of feed, with the exception of pasture, are given in pounds rather than in bushels or tons. All corn has been reduced to a shelled corn basis. The man hours include both regular daily chore labor and irregular labor such as tending sick animals, marketing livestock and livestock products, and hauling feed and bedding. The horse hours likewise include both regular and irregular work.

Local prices were used, insofar as possible, in determining the costs and returns. Marketable feeds were charged at local prices and non-marketable feeds on a comparative-feeding-value basis. No charge was made for straw or for corn stalk pasture. Man labor was figured at 15 cents per hour and horse work was charged to the individual farm at the rate determined for that farm. The shelter charge was based on the annual cost of the buildings housing livestock, prorated on the basis of the space occupied. The equipment charge is based upon the annual cost of the particular equipment used by that class of livestock. The expense for portable brooder houses and hog houses has been included in the equipment charge and omitted from the shelter charge. The equipment charge also includes a charge for any use made of the auto and truck. Interest has been calculated at five per cent on the average of the beginning and ending inventories. Miscellaneous cash costs include such cash expenses as veterinary fees, medicine, salt, minerals, hatching expense, fuel for brooders, incubators, and tank heaters, horseshoeing, sheep-shearing, etc. In arriving at the manure credit, consideration was given to the kind and the amount of feed consumed, the proportion of the fertilizing elements returned in the manure, and the value of manure when measured in terms of increased crop yields. Credit was allowed for manure produced, regardless of whether or not it was utilized.

The value of livestock production was determined by adding the sales, the products used in the house and the ending inventory and then deducting from this sum the sum of the beginning inventory and purchases. In the case of the different classes of cattle, transfers from one group to another were considered the same as purchases and sales. The weight produced was calculated in the same manner as the value produced except that weights were used instead of values.

In studying the tables and in considering the income from livestock, one should keep in mind that these are comparative figures and represent charges which are not all actual cash expenses. All feed, man labor, horse work, use of buildings and equipment, and interest on the investment have been charged to the enter-

prise, although they may represent very little direct cash outlay. Therefore, a minus return merely means that the particular class of livestock has failed to pay the usual market prices charged for the different factors. There may be no other more profitable alternative use for the buildings, much of the labor, or for the non-marketable feeds. A return above the price of marketable feeds and cash expenses may justify continued production although these figures fail to show a gain.

The individual farm figures have been arranged in order of increasing cost or decreasing returns, so that the farm with the lowest cost or the greatest return appears at the top of the table. In this way, each cooperator may quickly see how he compares with the other cooperators. The returns have been expressed in several ways. The gain is the amount left after deducting all the charges listed in the table. The return over feed cost is what is left after deducting the feed cost from the value of the product, excluding manure. In other words, the return over feed cost and the manure are what the farmer has to pay him for his labor, the horse work, shelter, equipment, interest and miscellaneous cash costs. The return per hour represents what the enterprise returned for each hour of man labor used by it, after all charges except labor had been deducted. In each case, a minus (-) indicates a failure to meet the particular expenses involved.

Cattle

The cattle enterprise was divided according to the separate classes and tables are presented for cows, feeder cattle, and miscellaneous or other cattle. Finally a table is shown for the entire cattle enterprise.

Cows: The cow herds were divided into three groups upon the basis of method of management. Herds of cows of dairy breeding which were managed with particular emphasis on butterfat production were called dairy herds. Herds composed of mixed breeds which were kept for raising calves as well as producing butterfat were classed as milk-and-beef herds. Herds which were kept primarily for the raising of beef calves were called beef-breeding herds. Because the major emphasis with both the dairy and the milk-and-beef herds was on butterfat production, the data for these two groups appear in the same tables (pages 7 and 8).

The costs and returns for the dairy and the milk-and-beef herds are for cows only. They neither include any feed or expense for the bull nor any credit for calves born. Due to the fact that calves were in some cases allowed to nurse for a short time, it was necessary to estimate their consumption of whole milk while nursing. It was assumed that the calves that were nursing received the same quantity of milk per day as those being hand fed. The value of the dairy products fed includes all milk and skimmilk fed to calves as well as to the other classes of livestock. The butterfat per cow was calculated by dividing the total butterfat utilized (including sales, used in the house, and fed to livestock) by the average number of cows in the herd. Calculated in this manner, the butterfat production may be materially less than that obtained by dairy herd improvement associations because in the latter case no allowance is made for waste and shrinkage.

In comparing the dairy herds with the milk-and-beef herds, it will be noticed that, on the average, the cows in the dairy herds received over twice as much grain and more roughage per cow than the cows in the milk-and-beef herds. In 1933 the dairy cows produced an average of 93 pounds of butterfat more than the milk-and-beef cows. Over fourteen per cent more man labor was used per cow in the dairy herds.

The difference between the dairy herds and the milk-and-beef herds in the return over all costs is larger in 1933 than in 1932. As the price of butterfat increases, the difference in favor of the dairy herds probably will increase. The

dairy cow furnishes a market for more labor and feed than the milk-and-beef cow. It is interesting to note that the largest gain as well as the largest loss occurred in the dairy herds.

Beef Breeding Herds: The beef breeding herds are kept primarily for raising beef calves. For this reason, the cost of the bull is included with the cost of the cows and the data are presented on a head basis for the entire breeding herd (page 9). The credit for dairy products fed does not include any milk or skimmilk fed to calves. The entire cost of the cows and bull, less any credit for manure or dairy products is charged against the calves raised. The cost per calf is obtained by dividing the net cost by the calves raised. This cost represents, approximately, the cost of a 400-pound feeder calf as the only additional cost would be a charge for the pasture and labor it received.

Feeder Cattle: This class includes the cattle being fattened for market and covers only the feeding period. A number of farms fattened one or two animals for sale or for home butchering. These farms were eliminated from the tables for feeder cattle (page 10) through the exclusion of all farms on which less than 1000 pounds gain in weight was attained during the feeding period. Due to the impossibility of determining the pork credit for feed picked up behind cattle, this item was omitted from all calculations. The fattening of cattle in 1933 consisted largely of the completion of the fattening of the cattle that were started on feed in 1932. Because of the shortage of feed, very few cattle were started on feed in 1933.

Other Cattle: Other cattle include all cattle except the cows and feeders. Data for other cattle are presented for the farms on which dairy or milk-and-beef herds were kept (pages 11 and 12). It represents primarily the heifers being raised for replacements altho in some cases one or two calves being fattened for sale or home butchering are also included.

All Cattle: Expenses and returns for the entire cattle enterprise, including cows, feeders and other cattle, calculated on an animal unit basis are presented (pages 13 and 14). In these statements any milk used by calves is omitted both from the feeds used and the credit for dairy products fed to live-stock. A study of the tables shows the lowest feed consumption per animal unit for the beef herds and the highest for the dairy herds. The amount of man labor used per animal unit was decidedly lower with the beef herds than with either of the other two groups. The shelter cost was higher for the dairy herds than the others, indicating the general use of more expensive shelter.

In 1933 the beef herds showed the smallest average loss and the dairy herds the largest. However, the difference was not large. The dairy herds gave the largest return over feed costs and the beef herds the smallest.

Sheep

In the tables (page 15) for sheep, the number of head is the average number of mature head for a year when two lambs up to six months of age are considered equal to one mature sheep. The weight produced per head was calculated by dividing the total weight produced by the average number of head. There was a net loss in weight on Farm 127. The fleece weight was calculated by dividing the total clip by the number of sheep sheared. The per cent death loss was arrived at by dividing the number of deaths by the total number of individual sheep or lambs, regardless of the length of time that they were on the farm. The lambs raised per ewe is the number of lambs raised to six months of age divided by the number of ewes at lambing time. The high death loss of mature sheep, primarily, was the result of old age and shortage of feed. Due to the low prices for aged ewes in

1932, many old ewes were kept for the 1933 lamb crop that ordinarily would have been sold. Many of these died during 1933.

With higher prices for both wool and sheep, the returns were much more favorable in 1933 than in 1932.

Hogs

Fall pigs were raised on three of the farms studied in 1933, but the proportion of the total pigs farrowed in the fall was so small as to be relatively insignificant. The pigs per litter is the number of pigs raised to six months of age plus the pigs sold or butchered at less than six months of age, divided by the number of farrowings. The average market weight is the average weight for all pigs and hogs sold. The price received per hundred pounds is the average price received for all hogs sold, including the premium received for the sows and pigs sold in the emergency hog reduction program. The pounds produced include any gain in weight for breeding hogs and likewise the expenses and receipts include those for the breeding herd. The data do not include any charge for feed salvaged from feeder cattle.

In the table of money costs and returns (page 17), the gain is the difference between the net expense and the selling price. The return over feed is obtained by deducting the feed cost from the selling price. Calculated in this manner, the effect of any gain or loss in inventory values due to a change in the price level is eliminated.

Although on the average there was a loss on hogs on all but five farms, there was some return over feed cost and on 60 per cent of the farms the return was large enough to pay the other costs and leave something for the labor.

Chickens

The data for chickens are presented on the basis of one hundred chickens (pages 18 and 19). In a few instances, a small number of ducks or geese were raised. In such cases, the feed, labor, other expenses and the receipts are included with the chickens and the number of chickens adjusted accordingly. The amount of meat produced was calculated in the same manner as for feeder cattle and for hogs. The cost per dozen eggs was calculated by deducting from the total cost all income from the production and sale of meat, and dividing the remainder by the number of dozens of eggs sold and used in the house. The selling price per dozen eggs was obtained by dividing the total cash receipts for eggs by the total number of dozens sold. Portable brooder houses were included with the equipment rather than with the buildings. For this reason, the equipment charge on a particular farm may be large and the shelter charge small or vice versa.

Turkeys

The turkey flocks on the farms studied were kept primarily for the production of meat. The production of turkey eggs for sale was of little importance. For this reason, the data for turkeys are presented on the basis of 100 pounds gain in weight (page 20). Less feed and labor were used per 100 pounds gain in weight in 1933 than in 1932. The average selling price was two cents per pound more in 1933 than in 1932. Returns were much higher in 1933 than in 1932.

Work Horses

The farms were divided into two groups for the presentation of the data on work horses (page 22). One group consists of the farms on which tractors were used for drawbar work and the other group is composed of the rest of the farms. The farms on which tractors were used were larger and raised more acres of crops per horse than the farms without tractors. In 1933 there was practically no difference between the two groups in the cost per horse. However, a larger number of hours worked on the farms without tractors resulted in a lower cost per hour.

Tractors

The tractors were divided into two classes, namely, two-plow and three-plow tractors. The number of four-plow tractors used was too small to provide any significant comparisons and for that reason were omitted. The costs are presented on the basis of a ten-hour day (page 23). The cost per hour can be obtained by dividing the cost per day by ten. The state gas tax is not included in the fuel cost as it was quite generally refunded. Miscellaneous cash includes cash paid for repairs, parts, etc. Depreciation is the difference between the value at the beginning and end of the year. Interest was calculated on the average of the beginning and ending inventories. There were no tractors bought during the year. Man labor is the value of the time the regular farm laborers spent repairing, servicing, etc. The use of the truck or auto in getting repairs, etc. for the tractor is charged on a mileage basis. The expenses as given do not include a charge for shelter. Some of the tractors were housed and some were not. In any case, the charge for shelter would be of minor importance.

Automobiles

The cost of operation of automobiles is presented on a per farm basis rather than per car (page 24). In six cases, the data involve more than one car. On a few farms the cars were traded during the year. The labor charge is the value of the time the regular farm workers spend repairing and servicing the cars. In a few cases, a small amount of horse work is included. Miscellaneous cash includes any cash paid for repair work, insurance, parts, tires, and greasing when hired done at a service station. All oil and gasoline, regardless of whether bought in bulk or small lots at service stations is included under gasoline and oil. The purchase price of cars bought is included in miscellaneous cash. The miles driven are speedometer miles in practically all cases with the exception that any miles travelled in getting repairs for the auto are omitted. It will be noticed that as with tractors, there is no charge for shelter. Because of the difficulty of obtaining a satisfactory charge for shelter and its comparatively minor importance, it was omitted from the calculations.

Factors of Cost and Return for Cows (Per Head) - Stevens County, 1933

*Farms divided into four groups on the basis of weight produced. Group A produced less than 500 pounds per farm, Group B produced from 500 to 1499 pounds, Group C produced from 1500 to 2499 pounds, and Group D 2500 pounds or over.

†Millfeeds include bran and middlings. Commercial feeds includes mash, scratch and oatmeal. Meat scraps also include tankage. Skimmlk includes dried buttermilk adjusted to a liquid basis.

‡Skimmlk equivalent is the pounds of skimmlk plus 17 times the pounds of tankage or meat scraps.

\$Poults hatched per 100 eggs set.
