Demographic and Economic Profiling of U.S. Demand for Probiotics: The Case of Drinkable Yogurt

Senarath Dharmasena and Oral Capps, Jr.

Abstract

Data from U.S. households for calendar year 2008 were used in examining demographic and economic factors affecting demand for drinkable yogurts using Heckman two-step procedure. Price, region, race and gender of household head were significant drivers of consumption of drinkable yogurts. Statistically significant sample selection bias was observed.

Key Words: Probiotics, drinkable yogurts, Nielsen HomeScan data, Heckman two-step

JEL Classification: D11, D12

Demographic and Economic Profiling of U.S. Demand for Probiotics:

The Case of Drinkable Yogurt

Senarath Dharmasena and Oral Capps, Jr.

Background:

There are many different types of non-alcoholic beverages available in the United States today compared to say the past decade. Functionality and health dimensions of beverages such as nutrient fortification, presence of beneficial cultured microorganisms, and enrichment with favorable fatty acids like Omega-3, are important considerations along with conventional economic factors (Ozer and Kirmaci, 2010; Beverage Marketing Corporation, 2008). Probiotics, beverages with beneficial cultured microorganisms, are the main bioactive product of the functional dairy food category and are still in the forefront of innovation (Ozer and Kirmaci, 2010; Champagne, 2009). At present, probiotics is a \$450 million market with roughly a 16% annual growth (Convenient Store News, 2010). More specifically, drinkable yogurt, defined as a dairy-based functional beverage that may or may not include fruit or fruit flavoring, is a probiotic non-alcoholic beverage which is relatively new and growing in the United States (Thompson *et al.*, 2007).

Knowledge of price sensitivity, substitutes/complements and demographic profiling in particular is important for manufacturers, retailers and advertisers of drinkable yogurts from a competitive intelligence standpoint and from the standpoint of strategic decision making. We could find two past studies pertaining to drinkable yogurts in the extant literature. Thompson *et al.*, 2007 investigated commercial strawberry drinkable yogurts linking sensory product characteristics to consumer preferences for Caucasian, African

American and Hispanic consumers in the United States. They observed variability in consumer acceptability across the three ethnic groups. Key drivers for all three groups were found to be natural strawberry flavor and sweet taste. Also, they found that drinkable yogurts with specific flavor and physical properties could be marketed to specific target market segments.

Davis *et al*, (2010) estimated own-price and cross-price elasticities for thirteen dairy product categories including drinkable yogurts using Nielsen HomeScan data for calendar year 2007. They used a censored almost ideal demand system model to come up with their estimates. The estimated compensated own-price elasticity for drinkable yogurt was -1.72. Age of the household head, presence of children, ethnicity and region were found to be significant demographic characteristics affecting the demand for drinkable yogurt.

Objectives

A thorough and a complete analysis of demand for drinkable yogurts is important primarily due to increasing growth in consumption in recent times and to the lack of information in the literature. In this light, specific objectives are: (1) to determine the factors affecting the decision to purchase drinkable yogurt, and (2) once the decision to purchase a drinkable yogurt is made, to determine the drivers of purchase volume.

Methodology

Initially, household purchases of drinkable yogurts (expenditure and quantity) and socio-economic-demographic characteristics are generated for each household in the Nielsen HomeScan Panel for calendar year 2008. As such we have total of 61,440 households, out of which only 11,546 unique households purchased drinkable yogurts. Using this data set, we

estimate demand for drinkable yogurts with adjustment to sample selection bias (Heckman, 1979).

Quantity data are standardized in terms of liquid ounces and expenditure data are expressed in terms of dollars. Then taking the ratio of expenditure to volume, we generate unit values (prices in dollars per ounce).

Factors hypothesized to affect the decision to buy drinkable yogurt and volume of drinkable yogurt purchased are: price of drinkable yogurt, income of the household head, and other demographic characteristics such as age, gender, employment and education status of the household head; region; race; Hispanic origin; age and presence of children.

Model Development, Procedures and Variables

Choice to purchase or not to purchase drinkable yogurt could be affected by price of drinkable yogurt and various demographic factors. This type of choice is a dichotomous discrete (buy or not-to buy or “one” if buy and “zero” if do not buy) and a probit model is used generally to model such a choice decision. The dependent variable is a zero one type dummy variable which is created to reflect the non-purchase or purchase respectively of drinkable yogurt. It is regressed on price and a host of demographic factors. Probit analysis will provide statistically significant findings of the decision to purchase drinkable yogurt.

Demographic and economic factors hypothesized to be affecting the decision to buy drinkable yogurt are listed on Table 1. Also, we provide different categories used in each factor along with base category for dummy variables.

The probit model for drinkable yogurt can be written as follows:

$$\begin{aligned}
\Pr(Y = 1 | x_i' \beta) = & \beta_1 + \beta_2 PRICE_i + \beta_3 AGEHH 2529_i + \beta_4 AGEHH 3034_i + \\
& \beta_5 AGEHH 3544_i + \beta_6 AGEHH 4554_i + \beta_7 AGEHH 5564_i + \beta_8 AGEHHGT 64_i + \\
& \beta_9 EMPHHPT_i + \beta_{10} EMPHHFT_i + \beta_{11} EDUHHHS_i + \beta_{12} EDUHHU_i + \\
& \beta_{13} EDUHHPC_i + \beta_{14} MIDWEST_i + \beta_{15} SOUTH_i + \\
& \beta_{16} WEST_i + \beta_{17} BLACK_i + \beta_{18} ASIAN_i + \\
& \beta_{19} OTHER_i + \beta_{20} HISP_YES_i + \beta_{21} AGEPCLT 6_ONLY_i + \\
& \beta_{22} AGEPC 6_12ONLY_i + \beta_{23} AGEPC13_17ONLY_i + \\
& \beta_{24} AGEPCLT 6_6_12ONLY_i + \beta_{25} AGEPCLT 6_13_17ONLY_i + \\
& \beta_{26} AGEPC 6_12AND13_17ONLY_i + \beta_{27} AGEPCLT 6_6_12AND13_17_i + \\
& \beta_{28} MHONLY_i + \beta_{29} FHONLY_i + \beta_{30} INCOME_i
\end{aligned} \tag{1}$$

where $i = 1, \dots, n$ is the number of households. Y corresponds to the decision to buy drinkable yogurt. Variables are defined in Table 1.

A common characteristic in micro level data (data gathered at consumer level such as at the individual or household level) is a situation where some consumers do not purchase some items during the sampling period and presence of them in the sample creates a zero consumption level for that data period. The data used in this study are gathered at household level and due to that it suffers from zero consumption data. As such we face a censored sample of data. Application of ordinary least squares (OLS) to estimate a regression with a limited dependent variable (such as in a censored sample like ours) usually give rise to biased estimates, even asymptotically (Kennedy, 2003). Removing all observations pertaining to zero purchases and estimating regression functions only for non-zero purchases too creates a bias in the estimates. This phenomenon also is known as *sample selection bias*. Heckman (1979) stated that not adjusting for sample selection may result in biased estimates of the demand parameters. Furthermore, Heckman (1979), discussed the sample selection bias as a specification error, and developed a simple consistent estimation method that eliminates the

specification error for the case of censored samples. It is known as Heckman-type correction procedure.

The first stage of the Heckman-two-step sample selection procedure, involves in decision to purchase drinkable yogurt. It is modeled through a probit model. A binary dependent variable is observed (purchase or not purchase), where purchase is represented by one (1) and not purchase is given by a zero (0). The latent selection equation can be written as follows;

$$Z_h = w_h' \gamma + \varepsilon_h \quad (2)$$

where Z_k represents a latent selection variable (buy or not to buy type dichotomous variable),

$$Z_h = \begin{cases} 1 & \text{if } Z_h > 0 \\ 0 & \text{if } Z_h < 0 \text{ or } = 0 \end{cases} \quad (3),$$

w_h is a vector of explanatory variables in the latent decision making variable, γ_h is a vector of parameters to be estimated in the decision making equation, ε_h is the error term, and $h = 1, 2, \dots, N$ is the number of observations (in our work the number of households in the sample) in the sample. Modeling above equation 2 through probit model gives us following relationships;

$$\Pr[Z_h = 1] = \phi(w_h, \gamma) \quad (4) \text{ and}$$

$$\Pr[Z_h = 0] = 1 - \phi(w_h, \gamma) \quad (5)$$

where ϕ is the normal cumulative probability distribution function (cdf). The first stage estimation provides estimates of γ and the inverse of the Mills Ratio (IMR hereinafter). We also generate the associated probability density function (pdf). Inverse of Mills Ratio is calculated taking the ratio of pdf to cdf. Mathematically, it is as follows;

$$\text{for } Z_k = 1, \text{ } IMR_h = \frac{\varphi(w_h \hat{\gamma})}{\phi(w_h \hat{\gamma})} \quad (6),$$

where φ represents the probability density function. Inverse mills ratio is a monotone decreasing function of the probability that an observation is selected into the sample, $\phi(w_k \hat{\gamma}_k)$ (Heckman, 1979). In particular,

$$\lim_{\phi(Z_{hi}) \rightarrow 1} IMR_h = 0 \quad (7)$$

$$\lim_{\phi(Z_{hi}) \rightarrow 0} IMR_h = \infty \quad (8)$$

$$\frac{\partial IMR_h}{\partial \phi(Z_h)} < 0 \quad (9)$$

The calculated IMR, will be used as an additional explanatory variable in the second stage volume equation, which takes care of the sample selection bias in the data. Second stage equation is given as follows;

$$E[Y_h | Z_h = 1] = X'_h \beta + \alpha \frac{\varphi(w_h \hat{\gamma})}{\phi(w_h \hat{\gamma})} \quad (10)$$

$$E[Y_h | Z_h = 1] = X'_h \beta + \alpha IMR_h \quad (11)$$

where X_k is a vector of explanatory variables considered in the second stage. Importantly, only observations associated with non-zero observations on Y_k are considered here. The IMR calculated using information retrieved from first stage probit model is used as an explanatory variable in the second stage (see equations 10 and 11 above). Presence of a sample selection bias in data will be communicated through statistical significance of the coefficient associated with IMR, i.e. α_k . If α_k is statistically not different from zero, we conclude that there is no sample selection bias in the data and result in the following regression model;

$$E[Y_h | Z_h = 1] = X'_h \beta_i \quad (12)$$

It is important to know that the explanatory variables in first stage and second stage equations may or may not be the same. In our work, the price variables in both equations do not. However, rest of the demographic variables is exactly the same in the first stage and second stage.

Choice of explanatory variables in the first and second stage has an implication on the derivation and interpretation of marginal effects associated with variables in the second stage. This is because in the second stage, we have the IMR term augmenting the regular regression function with other explanatory variables. Therefore, in calculating marginal effects, the influence of IMR and its associated regression coefficient on other regression coefficients have to be taken into consideration.

Suppose X_{kj} denote the j th regressor that is common to both first stage regressors, w_k and, second stage regressors, X_j . Differentiating equation 11 with respect to j th regressor, the marginal effect is given by the following relationship (following explanation is borrowed from Saha, Capps and Byrne (1997));

$$\frac{\partial E[Y_h | Z_h = 1]}{\partial X_{kj}} = \beta_{ij} + \alpha_i \frac{\partial(IM\hat{R}_{hi})}{\partial X_{hj}} \quad (13)$$

It is evident from 13 that marginal effect of the j th regressor on Y_{ki} consists of two parts: a change in X_j which affects the probability of consuming the commodity (this effect is

represented by $\frac{\partial(IM\hat{R}_{hi})}{\partial X_{hj}}$ in 13); a change in X_j which affects the level of consumption (or

expenditure of consumption) which is conditional upon the household choosing to consume

the i th commodity (this is represented by β_{ij} in 13). The former of the above two expression is

important, because the sign and magnitude of the marginal effect depends not only on the β_{ij} ,

but also that of the $\frac{\partial(IMR_{hi})}{\partial X_{hj}}$. According to Saha, Capps and Byrne (1997), after some

simplification we get arrive at the following relationship for the Heckman second stage marginal effects,

$$ME_{kj}^{\hat{}} = \frac{\partial E[y_k | Z = 1]}{\partial X_{kj}} = \beta_j - \alpha \gamma_{ij} \{W \gamma IMR_k + (IMR_k)^2\} \quad (14)$$

In general the marginal effect $ME_{kj}^{\hat{}} \neq \hat{\beta}_j$; however the only case where $ME_{kj}^{\hat{}} = \hat{\beta}_j$ is where $\hat{\alpha} = 0$ which is a situation where the errors in the first-stage and second-stage estimation equations have zero covariance. It must be noted that the $ME_{kj}^{\hat{}}$ estimation depends on a local set of co-ordinates. Therefore, we estimate the $ME_{kj}^{\hat{}}$ at the sample means. Following equation 14 shows this result. For simplicity, let us denote IMR in the letter λ .

$$ME_{kj}^{\hat{}} |_{sample\ mean} = \hat{\beta}_j - \hat{\alpha}_i \hat{\gamma}_j \{(\bar{W} \hat{\gamma}) \bar{\lambda} + \bar{\lambda}^2\} \quad (15)$$

where \bar{W} denotes the vector of regressor sample means in the probit equation (the first stage equation of the Heckman two-step model and

$$\bar{\lambda} = \frac{\varphi(\bar{W} \hat{\gamma})}{\phi(\bar{W} \hat{\gamma})} \quad (16)$$

is the inverse Mills ratio evaluated at those means.

The Heckman two-step demand model for drinkable yogurt can be written as follows:

$$\begin{aligned}
q_i = & \beta_1 + \beta_2 P_i + \beta_3 AGEHH_{2529}_i + \beta_4 AGEHH_{3034}_i + \\
& \beta_5 AGEHH_{3544}_i + \beta_6 AGEHH_{4554}_i + \beta_7 AGEHH_{5564}_i + \beta_8 AGEHH_{GT64}_i + \\
& \beta_9 EMPHHPT_i + \beta_{10} EMPHHFT_i + \beta_{11} EDUHHHS_i + \beta_{12} EDUHHU_i + \\
& \beta_{13} EDUHHPC_i + \beta_{14} REG_CENTRAL_i + \beta_{15} REG_SOUTH_i + \\
& \beta_{16} REG_WEST_i + \beta_{17} RACE_BLACK_i + \beta_{18} RACE_ORIENTAL_i + \\
& \beta_{19} RACE_OTHER_i + \beta_{20} HISP_YES_i + \beta_{21} AGEPC6_ONLY_i + \\
& \beta_{22} AGEPC6_12ONLY_i + \beta_{23} AGEPC13_17ONLY_i + \\
& \beta_{24} AGEPC6_6_12ONLY_i + \beta_{25} AGEPC6_13_17ONLY_i + \\
& \beta_{26} AGEPC6_12AND13_17ONLY_i + \beta_{27} AGEPC6_6_12AND13_17_i + \\
& \beta_{28} MHONLY_i + \beta_{29} FHONLY_i + \beta_{30} INCOME_i + \alpha_i IMR + \varepsilon_i
\end{aligned} \tag{17}$$

where $i = 1, \dots, n$ is the number of observations (households in our work) in the model. q_i corresponds to the quantity of purchase of drinkable yogurt and P_i variable represent the price of drinkable yogurt. We have defined the variables in the above equation 17 in Table 1. In the equation 17, IMR stands for the inverse Mills ratio and α_i corresponds to the coefficient associated with IMR . Presence of sample selection bias is determined looking at the significance of α_i . If we have sample selection bias, we have to do an adjustment to the coefficient estimates in the second stage estimation in trying to get at correct marginal effects. Procedure to adjust for marginal effects was elaborated in the preceding section.

As such, we will calculate marginal effects associated with each explanatory variable. The level of significance we will be using in this study is 0.05. We further conduct an F -test for demographic variable categories to find statistically significant demographics.

Results and Discussion

Preliminary investigations using transactions data reveal that the market penetration for drinkable yogurt is 19 percent. The average at-home quantity of DY consumed is 133 ounces per household per year and the average price is \$0.14 per ounce. Factors affecting the probability of purchase of drinkable yogurt are price of drinkable yogurt, income of the

household head, employment status of the household head, education status of the household head, region, race, age and presence of children, and gender of the household head. Factors affecting the volume of purchase of drinkable yogurt are price of drinkable yogurt, region, race, and gender of the household head. The own-price elasticity of demand for drinkable yogurt is estimated to be -0.68. A significant sample selection bias is observed in considering the demand for drinkable yogurts.

Table 1 Description of the Right-Hand Side Variables Used in the Econometric Analysis

Variable	Explanation
PRICE	Price of Drinkable yogurt
<i>AGEHHLT25</i>	<i>Age of Household Head less than 25 years (Base category)</i>
AGEHH2529	Age of Household Head between 25-29 years
AGEHH3034	Age of household Head between 30-34 years
AGEHH3544	Age of household Head between 35-44 years
AGEHH4554	Age of household Head between 45-54 years
AGEHH5564	Age of household Head between 55-64 years
AGEHHGT64	Age of household Head greater than 64 years
<i>EMPHHNF</i>	<i>Household Head not employed for full pay (Base category)</i>
EMPHHPT	Household Head Part-time Employed
EMPHHFT	household Head Full-time Employed
<i>EDUHHLTHS</i>	<i>Education of Household Head: Less than high school (Base category)</i>
EDUHHHS	Education of Household Head: High school only
EDUHHU	Education of Household Head: Undergraduate only
EDUHHPC	Education of Household Head: Some post-college
<i>EAST</i>	<i>Region: East (Base category)</i>
MIDWEST	Region: Central (Midwest)
SOUTH	Region South
WEST	Region West
<i>WHITE</i>	<i>Race White (Base category)</i>
BLACK	Race Black
ASIAN	Race Oriental
RACE_OTHER	Race Other (non-Black, non-White, non-Oriental)
<i>HISP_NO</i>	<i>Non-Hispanic Ethnicity (Base category)</i>
HISP_YES	Hispanic Ethnicity

Table 1 Continued....

Variable	Explanation
<i>NPCLT_18</i>	<i>No Child less than 18 years (Base category)</i>
AGEPCLT6_ONLY	Age and Presence of Children less than 6-years
AGEPC6_12ONLY	Age and Presence of Children between 6-12 years
AGEPC13_17ONLY	Age and Presence of Children between 13-17 years
AGEPCLT6_6_12ONLY	Age and Presence of Children less than 6 and 6-12 years
AGEPCLT6_13_17ONLY	Age and Presence of Children less than 6 and 13-17 years
